LETTER TO THE EDITOR

Seeing through the eyes of patients with age-related macular degeneration

Dear Editor,

Age-related macular degeneration (AMD) is a severe ocular disease characterised by progressive deterioration of the macula, the most sensitive central part of the retina.1 It is the most common cause of irreversible vision loss among individuals aged ≥60 years in developed countries,2 and accounts for about 6% of all causes of blindness worldwide.3 A population-based cross-sectional study in Singapore revealed its age-standardised prevalence was 5.1% (95% confidence interval [CI] 4.6–5.5) for early AMD and 0.5% (95% CI 0.4–0.6) for late AMD.4 Given Singapore’s rapidly ageing population, the prevalence of AMD among its residents aged ≥40 years is projected to increase by 54% from 125,274 (95% CI 123,241–127,307) cases in 2015 to 193,435 (190,295–196,575) cases in 2040.5

Patients with AMD often have relative scotomas and metamorphopsia in their central visual field. The Amsler grid is an inexpensive and rapid test designed to specifically test visual field defects in the central 10 degrees.6 Utilising a suprathreshold target to analyse the central vision, it is good for detecting metamorphopsia but is not sensitive for the detection of relative scotomas.7 Attempts have been made to characterise the size, shape, slope and extent of scotomas using a 3-dimensional computer-automated threshold Amsler grid test, which may have the potential as a screening tool for the early diagnosis of AMD.8

The Snellen visual acuity chart is the most commonly used chart to evaluate vision in clinical practice. In the last few decades, the Early Treatment Diabetic Retinopathy Study chart has become the gold standard test to measure visual acuity and evaluate eyes with macular disease in clinical trials.9 However, these tests are non-timed and thus may not simulate real-world situations such as driving, where there is a limited amount of time to recognise objects, read signs and make important vision-based decisions.10 This is important for patients with AMD because they find difficulties with many vision tasks that are time-dependent such as reading, driving and recognising faces in fluid social situations.11

In an effort to realistically depict how AMD patients see themselves in the mirror, one of us (AH), a professional portrait artist, has painted 17 portraits of individuals suffering from varying severities of AMD as seen through the patients’ own eyes (Fig. 1). The portraits were conceptualised by first obtaining detailed information from an AMD patient on the specific visual abnormalities he or she experienced, such as metamorphopsia and relative scotoma through a face-to-face interview. Based on this information, a photograph of the patient was manipulated to match the patient’s perception of himself or herself in the mirror and a preliminary portrait of the patient was sketched. The portrait was then adjusted to reflect more accurately the patient’s perception. Re-painting and verification by the patient were repeated several times before the portrait was finalised. Interestingly, we found that AMD patients who had their portraits painted rarely reported image distortion but more often reported scotoma(s).

To showcase these portraits, we organised a unique public art exhibition in conjunction with the AMD Awareness Week campaign in Singapore in 2010.12 The exhibition was very well-received and we believe such artworks are useful to raise public awareness of AMD and enable a more accurate perception and understanding of the visual problems experienced by AMD patients in their daily lives.13-15
